One of the great conceptual novelties of recent years in the life sciences is systems biology. Although molecular biology is considered to have been founded by physicists, this circumstance did not result in a quantitative culture and the accurate, standardized descriptive language characteristic of the “hard sciences”. With very few exceptions, the biosciences that have developed since that time seldom took the opportunity to formalize the mechanisms and functions of living systems using accurate languages and codes. Systems biology occupies this niche by analysing biological entities as comprehensible physicochemical objects with a functioning logic that can be modelled, understood and reshaped. By the same token, systems biology is not just a contemporary update of the recombinant DNA technologies of the past 30 years, with descriptive language imported from electrical and industrial engineering. It is also a new interpretative key for living systems as well as a declaration of intent regarding the use and reprogramming of biological objects for human benefit. In the same way that scientific chemistry, as initiated by Lavoisier, evolved into the chemical engineering that is the basis of our industrial society, biology has acquired a transforming potential that could lead to a type of industry and economy very different from the current paradigm. The CNB SysBio Programme figures in the contemporary landscape by developing active research lines in environmental genomics, network biology, systemic computation and metabolic engineering. This framework (which many consider a veritable paradigm shift) seeks to address the complexity of living systems as such, not to divide them into smaller parts (at difference from the reductionism of molecular biology). Systems biology offers remarkable scientific and technological potential for the field of biomedicine and for industrial, agricultural and environmental biotechnology.

HEAD OF PROGRAMME

Víctor de Lorenzo

OUR RESEARCH GROUPS

1. Molecular environmental microbiology
   Víctor de Lorenzo

2. Evolutionary systems
   Susanna Manrubia

3. Computational systems biology
   Florencio Pazos

4. Logic of genomic systems
   Juan F. Poyatos

5. Microbiome analysis
   Javier Tamames and Carlos Pedrós-Alió

Top: Complex regulatory networks can be recreated as circuits of logic gates. The image shows the complex genetic device that controls expression of genes for degradation of m-xylene in the environmental bacterium *Pseudomonas putida*.

Bottom: Heat maps show relationship between resistance to the herbicide phosphinothricin and exposure to arsenic in the soil bacterium *P. putida*. 
Our longstanding mission is to produce biological agents for biosensing, remediation and (when possible) valorization of chemical waste from urban and industrial activities that is otherwise dumped into the environment. To this end, we explore and capitalize on the interface between environmental microbiology and synthetic biology. Our workhorse is the soil bacterium 

Pseudomonas putida, which combines the ease of genetic programming typical of Escherichia coli with the safety, robustness and metabolic capabilities required in whole-cell catalysts for applications in harsh biotechnological settings. Specific activities include [i] development of 

P. putida as a reliable chassis for implantation of genetic and metabolic circuits. This involves profound editing of the extant genome of this microorganism to enhance desirable properties and eliminate drawbacks, as well as exploitation of surface-display systems for designing complex catalytic properties, altogether separated from cell metabolism, and the design of artificial communities by ectopic adhesins. [ii] Development of camel antibodies as tools for metabolic and regulatory engineering of 

P. putida. Various expression systems permit the targeting of camelid VHH fragments to the intracellular compartment, the periplasm or the external medium of the cells. This allows selective perturbations of chosen metabolic routes to enhance desired metabolic and regulatory qualities of bacteria. [iii] Genetic tools for deep refactoring of metabolic properties of 

P. putida. The list of new assets we are developing includes a large collection of standardized plasmid and transposon vectors as well as dedicated reporter systems for parameterization of gene expression flow and switching entire metabolic regimes. [iv] The Tol system borne by plasmid pWW0 as a reference for metabolic circuit implantation. The two operons for toluene and m-xylene biodegradation encoded in pWW0 offer a natural case of expansion of the metabolic repertoire of environmental bacteria through acquisition of new genes. [v] Deep metabolic engineering of 

P. putida. Currents efforts attempt to develop strains that can be entirely programmed to deliver catalytic phenotypes of choice after exposure to and computation of external and internal cues.

PoPs (DNA polymerase per second passing through a promoter) and RiPs (ribosome per second going through an mRNA).
The main interest of our group is the theoretical study of evolutionary systems of different kinds. We develop models inspired by the phenomenology observed in natural systems, chiefly molecular populations, viruses, and interacting agents at the cellular level and up. Our approach addresses the study of fundamental properties of adapting systems—with strong emphasis on their evolutionary origin—or, more specifically, tries to reproduce and eventually, to predict the response of such populations to endogenous and exogenous changes. In this context, we analyse the properties of the genotype-phenotype map through models such as the folded state of RNA sequences, focusing on the topological structure of neutral networks of genotypes and its relevance in adaptation and molecular innovation.

Another main goal is to understand the survival strategies of viruses, including the relevance of multipartite genomes or the ecological effect of viral satellites. At a higher organizational level, we are also interested in modelization of the interaction between agents organized in networks that vie for resources, food, or mates, as competitive interactions represent one of the driving forces behind evolution and natural selection in biological systems. Finally, we explore the application of complex systems to biotechnology through the development of analysis techniques with environmental and health purposes. We have applied graph theory to antibody microarrays to improve the characterization of experimental samples, with direct application to allergy control, toxin detection in fresh water ecosystems, and identification of potential biomarkers in space missions. Our studies of viral response to antiviral treatments have determined optimal modes of drug administration to minimize viral load and mutant escape.
Our group is interested in different aspects of bioinformatics, computational biology and systems biology. Our goal is to obtain new biological knowledge with an in silico approach that complements the in vivo and in vitro methodologies of biology. This mainly involves mining the massive amounts of information stored in biological databases. Besides our lines of scientific research, we also collaborate with experimental groups by providing them with bioinformatics support for their specific needs, and participate in different teaching projects.

We have developed evolutionary-based methods for predicting sites with functional importance in protein sequences and structures. These methods are based on the fact that functional sites are subject to certain evolutionary constraints whose landmarks can be detected on multiple sequence alignments.

The biological functions of many proteins can only be explained in the context of their relationships with others. We have developed evolutionary-based methods for predicting interaction partners, which have been adopted by the scientific community. These methods are based mainly on the hypothesis that interacting or functionally related proteins adapt to each other during the evolutionary process (co-evolution). We try to detect the landmarks that this co-evolutionary process left in the sequences and structures of the proteins.

The study of living systems from a network perspective is providing new biological knowledge that could never have been obtained from the study of individual components (genes, proteins, etc.), no matter how detailed. This new strategy is needed to complement the intrinsic limitations of a reductionist approach that cannot keep up with the complexity of living systems. We are studying metabolic networks (central metabolism and biodegradation) and protein interaction networks with this new top-down approach. We also recently began to study human diseases using these new systemic and network-based approaches.

López D, Pazos F. Protein functional features are reflected in the patterns of mRNA translation speed. BMC Genomics 2015; 16: 513

We have focused on quantitatively understanding the functional and evolutionary implications of different modes of gene expression control. Our work could further motivate the search for fundamental design principles of gene regulation by non-coding RNAs, demonstrate how the application of concepts from information theory lead to more precise, quantitative understanding of cell systems, and uncover new general dynamic properties of interlinked feedback circuits applicable to bioengineering of synthetic units. Specifically, we studied:

- A simple non-coding RNA circuit, known as riboregulator, to predict its behaviour and mutational landscape. We designed a synthetic riboregulator to then introduce a theoretical framework able to predict expression parameters and the functional consequences of mutations on the corresponding RNA sequences. This framework was tested experimentally by characterization of an RNA switch following the theoretical proposal.

- An original framework based on information theory to examine how multiple copies of a decision-making regulatory circuit turn noise into a beneficial feature, which suggests a novel adaptive function of genetic redundancy (Fig. 1). We tested how genetic redundancies allow information to be maximized, how this effect depends on device specifications, and the interdependence among them. The theory was corroborated by experimental data in several systems.

- An operation regime of a regulatory circuit exhibiting antagonistic positive and negative autoregulatory feedback loops. As a model system, we considered the circuit that controls the multiple antibiotic resistance phenotype in *Escherichia coli*. We combined theory with quantitative experiments at the population and single-cell levels (Fig. 2). In this architecture, weak positive feedback serves to increase the transcription rate “on the fly” due to derepression of the system and concomitant expression of the activator. This accelerates the response dynamics and limits the heterogeneity of the induced phenotype within a population.

**SELECTED PUBLICATIONS**

Illustration depicting how intrinsic noise, genetic redundancy, and heterogeneity increase transmission of information by cellular decision-making circuit devices (working as threshold systems). Extrinsic noise and crosstalk among redundant units become limiting factors instead.
We are interested in describing the rules that govern the assembly of microbial communities. Our objective is to achieve predictive capacity of the function of these communities, given their composition and the environmental factors in play. This will allow us to determine the conditions that favour particular combinations of species able to fulfil specific goals in biotechnological, clinical and ecological scenarios.

By combining information on the diversity and function of natural microbial communities, obtained by high-throughput sequencing, with mathematical modelling of the microbial metabolism, we try to understand how specific environmental changes influence the composition and function of the community.

We also aim to understand the ecology of aquatic microorganisms. We want to learn how microorganisms survive in unusual environments and thus derive clues regarding the function of more conventional habitats. Another interest is to comprehend the diversity of microorganisms, and especially the mechanisms that maintain a large variety of rare bacteria species in aquatic ecosystems.

Metagenomics and metatranscriptomics play a pivotal role in our work. Using these approaches, we obtain information on the presence and activity of specific organisms and their functions. We can also evaluate changes in composition, function and activity in response to environmental perturbations. These techniques also allow us to recover quasi-complete genomes that can be used to generate metabolic models for the species involved.
